

# SPECIAL PROJECT PROGRESS REPORT

Progress Reports should be 2 to 10 pages in length, depending on importance of the project. All the following mandatory information needs to be provided.

**Reporting year** 2019

**Project Title:** High-Resolution EC-Earth Simulations - Ireland's Contribution to CMIP6

**Computer Project Account:** spienola

**Principal Investigator(s):** Dr Paul Nolan<sup>1,2</sup>  
Dr Jonathan McGovern<sup>2</sup>

**Affiliation:** <sup>1</sup>Irish Centre for High-End Computing and  
<sup>2</sup>Climate Research Department, Met Éireann

**Name of ECMWF scientist(s) collaborating to the project (if applicable)** N/A

**Start date of the project:** 01/01/2019

**Expected end date:** 31/12/2021

**Computer resources allocated/used for the current year and the previous one (if applicable)**

Please answer for all project resources

## Summary of project objectives

The goal of the research project is to simulate the effects of climate change at the global scale using the EC-Earth model. After discussion with the EC-Earth community, the PI committed to running the following EC-Earth CMIP6 contributions:

- 5 x T255-ORCA1L75 AOGCM CMIP6 Historical Simulations, 1850-2014
- 20 x T255-ORCA1L75 CMIP6 (5 x SSP1-2.6, SSP2-4.5, SSP3-7.0 & SSP5-8.5), 2015-2100

The simulations are now complete, the data “cmor-ised” and are in the process of being hosted and shared on the ICHEC ESGF node.

## Summary of problems encountered (if any)

The CMIP6 version EC-Earth was slow to run on cca so a careful scale testing was completed to determine the optimal configuration. Table 1 presents scaling statistics for EC-Earth GCM (3.3.0-cmip6-historical) on ECMWF cca using intel-mpi. The simulated time is one month. Three “forking” strategies are considered; no-forking (not shown), all nodes shared (ShareAll) and dedicated nodes for IFS with other components sharing nodes (not shown). rnf\_numproc is set to 1 in all cases and the Elpin land removal tool was implemented. The configuration highlighted in blue was found to be optimal.

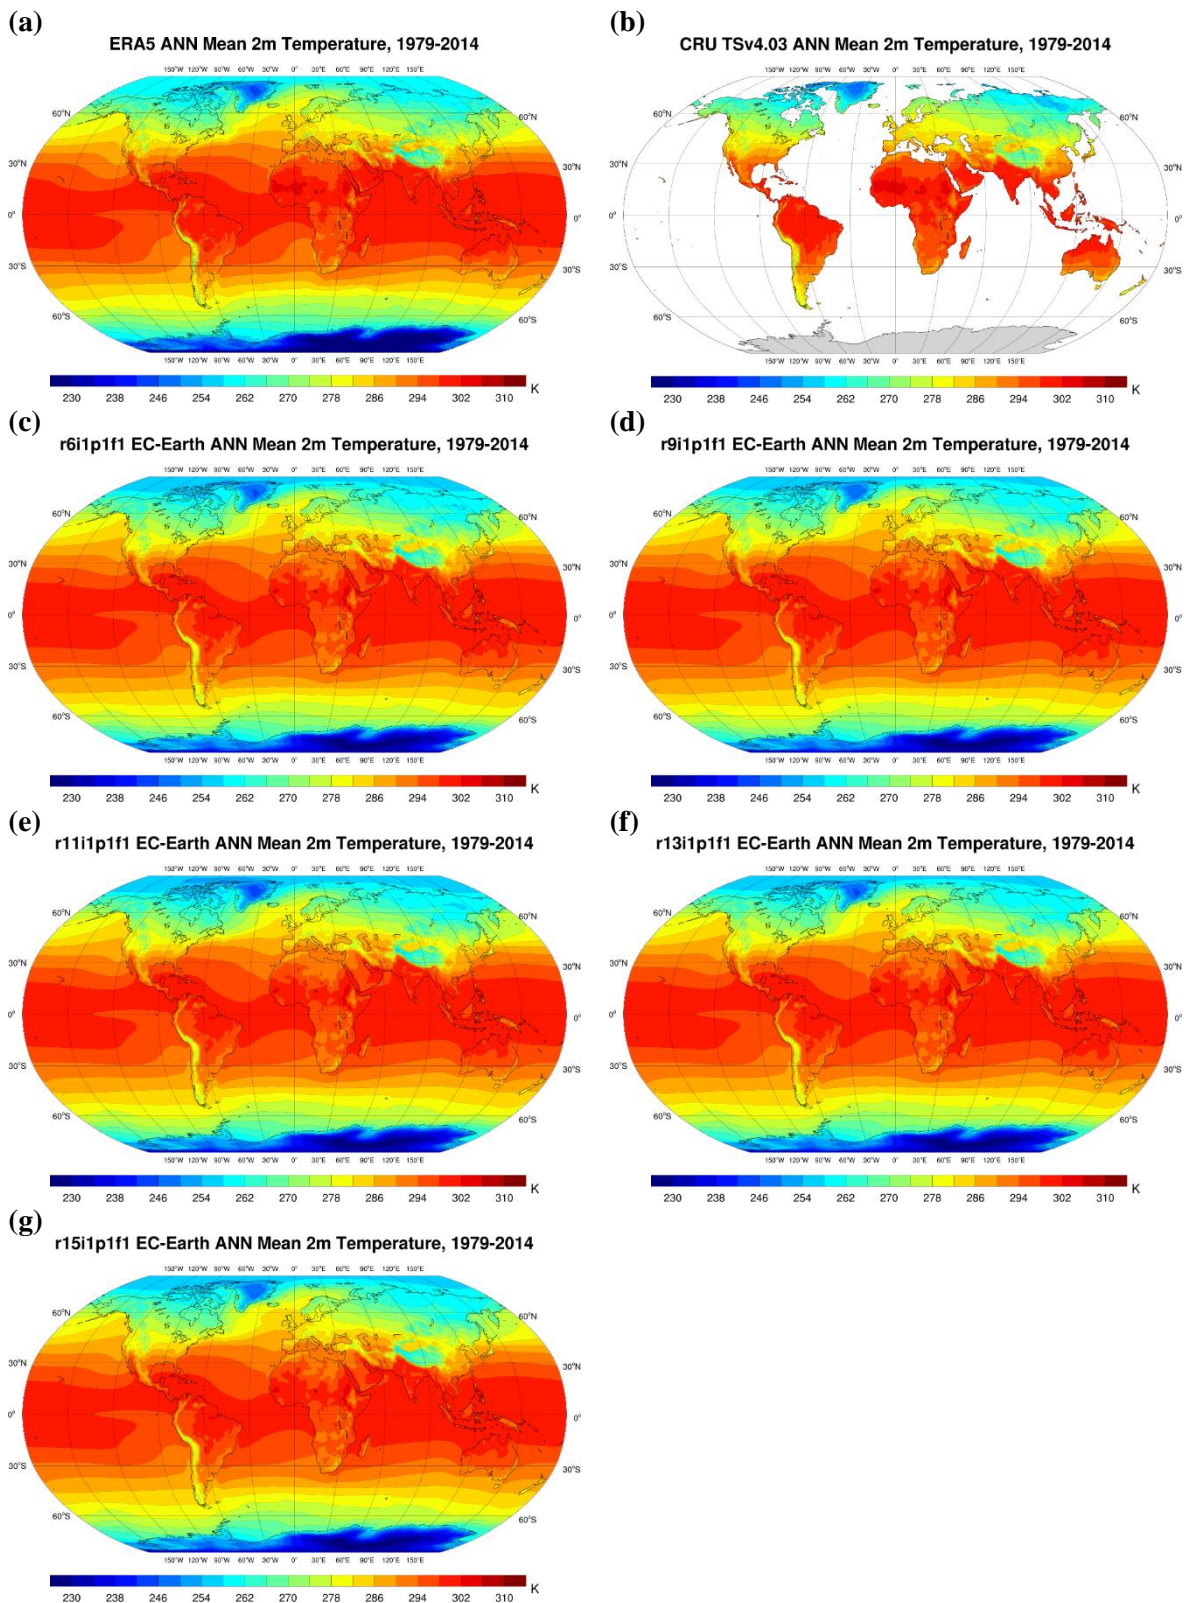

| Fork     | # IFS cores         | # nemo cores | # Nodes   | Time (mm:ss) | SBUs             | SYPD        | CHPSY       |

**Table 1. EC-Earth Scaling On ECMWF/cca**

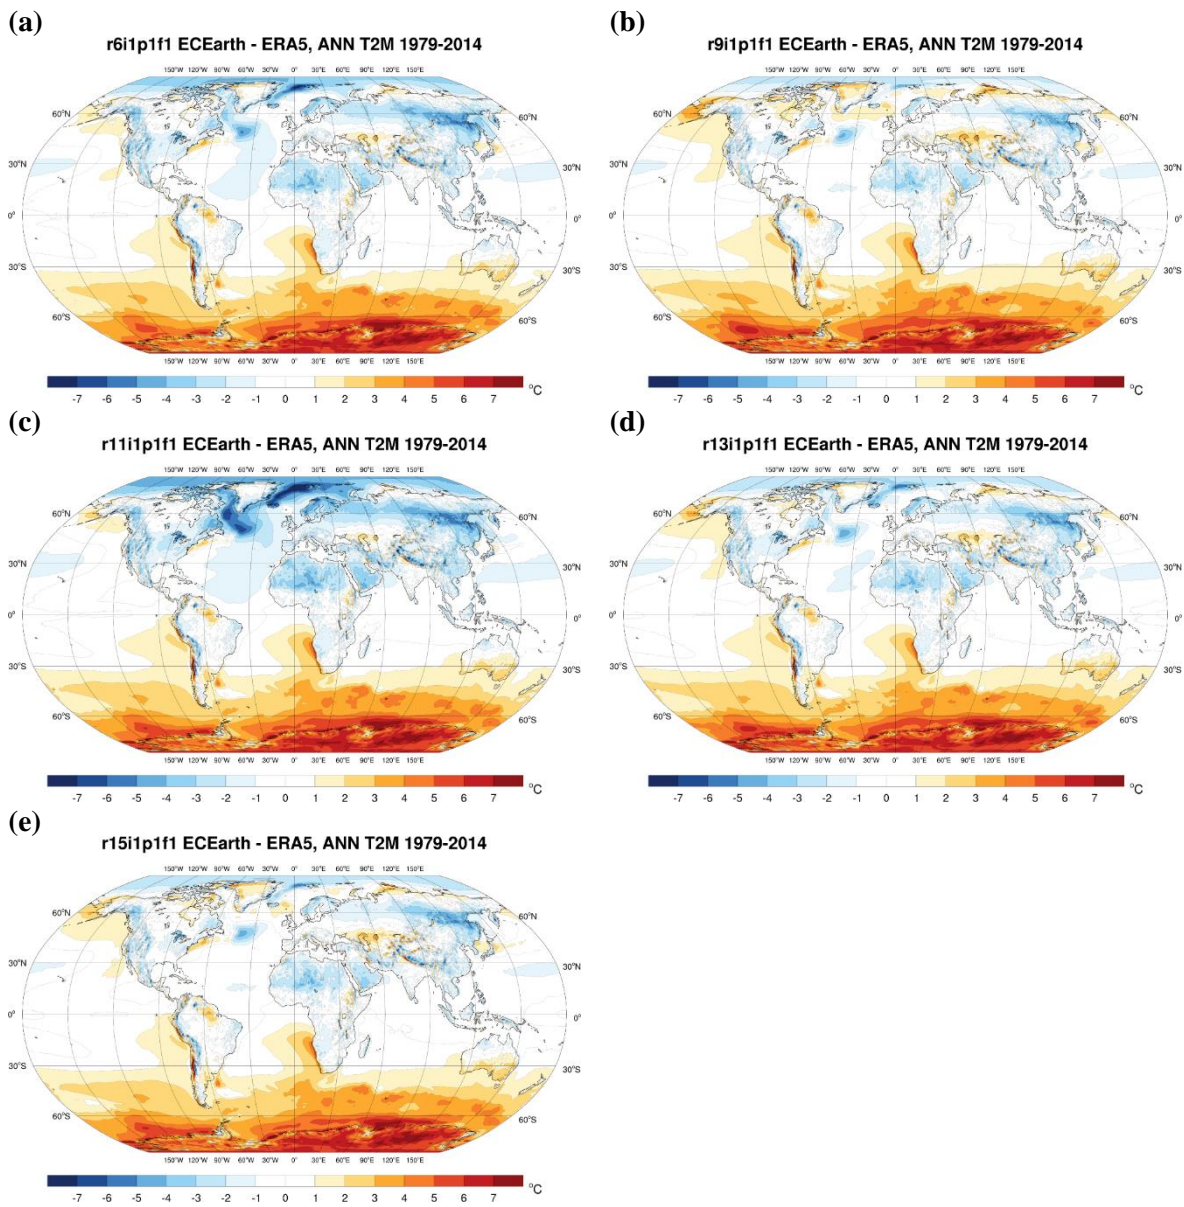

## Summary of results of the current year (from July of previous year to June of current year)

### 1. EC-Earth Validations.

The EC-Earth ensemble members were validated by comparing the five historical ensemble members (r6i1p1f1, r9i1p1f1, r11i1p1f1, r13i1p1f1 and r15i1p1f1) with CRU observational and ECMWF ERA5 reanalysis datasets. Figure 1 presents the mean 2m temperature for the period, 1979-2014 for ERA5, CRU and each of the five EC-Earth ensemble members. The EC-Earth models exhibits a general cold bias over land and a warm bias over the Southern Ocean (Figure 2). Tables 2 & 3 present the annual & seasonal bias and MAE global average statistics for ERA5 (1979-2014) and CRU (1901-2014), respectively. The EC-Earth ensemble members exhibit a warm (cold) biased compared to ERA5 (CRU). Similarly, precipitation validations are presented in Figure 3 and Tables 4 & 5 and demonstrate that the EC-Earth model performs well.

**Figure 1.** Annual Mean 2m Temperature 1979-2014; (a) ERA5 Reanalysis, (b) CRU ts4.03 Observations, (c) EC-Earth r6i1p1f1, (d) EC-Earth r9i1p1f1, (e) EC-Earth r11i1p1f1, (f) EC-Earth r13i1p1f1 and (g) EC-Earth r15i1p1f1

## 2. EC-Earth Climate Projections

Figure 4 presents the spatial distribution of annual mean 2m temperature projections for each of the four SSPs for the 30-year period 2041-2070 (relative to 1981-2010). The corresponding 2071-2100 projections are presented in Figure 5. Note that for each figure, the mean of the five ensemble members is considered. The largest increases in temperatures are noted over the land masses, in particular the northern-most regions and the Arctic. Projections of temperature range from  $\sim 0.5^{\circ}\text{C}$  over the Southern Ocean for 2041-2070 SSP1-2.6 (Figure 4a) to  $\sim 18^{\circ}\text{C}$  over the Arctic for the 2071-2100 SSP5-8.5 (Figure 5d).

Projections for DJF (not shown) follow a similar trend with the exception that increases over the northern land masses and the Arctic are enhanced. The projections for JJA (not shown) follow a similar trend to the annual projections with the exception that increases over the northern land masses and the Arctic are diminished whereas increases over Antarctica are enhanced.

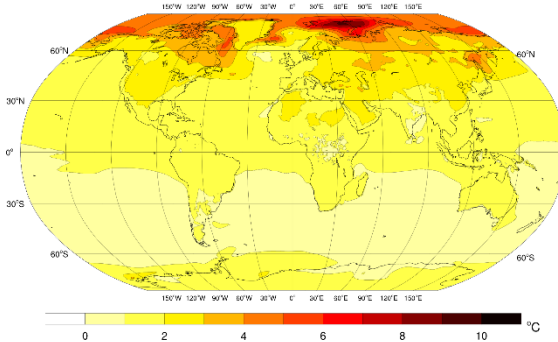

The mean global annual temperature anomalies (relative to 1981-2010) for all five historical (1850-2014) and twenty SSPs (2015-2100) are presented in Figure 6. The bold lines represent the ensemble mean. All ensemble members show a steady increase in temperature from around 2000 with a noticeable divergence between the SSPs from around 2050. By the year 2100, the global mean temperature is projected to increase by approximately  $1.5^{\circ}\text{C}$ ,  $2.8^{\circ}\text{C}$ ,  $4.2^{\circ}\text{C}$  and  $5.5^{\circ}\text{C}$  for SSP1-2.6, SSP2-4.5, SSP3-7.0 and SSP5-8.5, respectively. The small spread between the individual ensemble members demonstrates a high level of agreement and adds a measure of confidence to the projections.

Figure 7 presented the spatial distribution of annual precipitation projections (%) for each of the four SSPs for the 2041-2070 period. The corresponding projections for 2071-2100 are presented in Figure 8. The general trend is for an increase in precipitation with the exception of the North Atlantic region south of Iceland and regions just north and south of the equator including North Africa and large parts of South America and South Africa. Southern Europe and the Mediterranean show a drying for the end-of-century SSP3-7.0 & SSP5-8.5 projections.

Precipitation projections for DJF (not shown) follow a similar (but enhanced) trend to the annual projections. However, Europe and the Mediterranean are projected to be wetter under all SSPs. The projections for JJA (not shown) follow a similar trend to the annual projections with a general increase in precipitation in most regions and an enhanced drying over Southern Europe, North America, South America and South Africa. For JJC, there is no drying projected in the Atlantic region south of Iceland.

The mean global annual precipitation anomalies (relative to 1981-2010) for all five historical (1850-2014) and twenty SSPs (2015-2100) are presented in Figure 9. The bold lines represent the ensemble mean. All ensemble members show a steady increase in precipitation from around 2000 with a noticeable divergence between the SSPs around 2060. By the year 2100, global mean precipitation is projected to increase by approximately 4%, 6%, 8% and 10% for SSP1-2.6, SSP2-4.5, SSP3-7.0 and SSP5-8.5, respectively.

#### Summary of plans for the continuation of the project

The EC-Earth analysis work will continue and all data will be hosted and shared on the ICHEC ESGF node. The PI will investigate if additional EC-Earth simulations will be run. This additional simulations will be decided after consultation with the EC-Earth community and will consist of EC-Earth-Veg and/or EC-Earth HighResMIP contributions.

The EC-Earth data will be dynamically downscaled using COSMO-CLM, WRF and HCLim Regional Climate Models.
